Ai-usage-Cipherdrop.md — Summary Section

```

Help me write the AI Usage Summary section for a university project report.

I used AI tools to help build a security web application.

Here is what I actually did:

Tools used: [ChatGPT, visual building, mermaid AI graph building, Claude code]

Used AI for: [Building design graphs and attack diagrams, debugging, helping with frontend, managing congruency of backend, maintaining format and generating ideas for design, along with test cases]

What AI got right: [Locating buggy code and frontend were some of the best, it could also create test cases pretty easily]

What AI got wrong or required correction: [AI required correction in several areas but mainly debugging, frontend issues with style, and folder formatting of files or variable names being done incorrectly in backend]

Security-critical code we chose not to use AI for: [Password management and encryption, we chose not to use it for that since its one of the main methods of security along with some authorization levels.]

Write a clear, honest 1–2 page summary covering these points. Avoid making AI sound

either perfect or useless — the goal is an honest reflection on what AI assistance

actually contributed to the project.
```

There were many cases where we would prompt a debug for a specific line of code and it would end up making that line 2x longer and somehow failing to debug it anyway. The main correction to this was using a separate AI model or fixing it yourself after telling AI to give instructions if needed. It was never entirely useless for the project and worked great for the frontend, while most of the AI frontend can be very similar in structure (after all its taking from millions of sources and mixing them down to the same thing basically). A lot of the things that AI had helped with included frontend and debugging, while the debugging had some issues it was still a nice way to have a 50/50 chance of instantly fixing a bug. It was also really good at spotting bugs, its very annoying to go through hundreds of lines of code and figure out what exactly is wrong but by copy and pasting it in, or using the terminal option for certain AI algorithms, you can have it pinpoint specific lines of code that are required to be fixed or could be problematic in the future. We also had used AI for organization and management of folders, specifically the frontend folders (including things like html and especially json), json folders and anything related to java script is knowledge that we were lacking in when coming to this project so having AI help with that was needed.

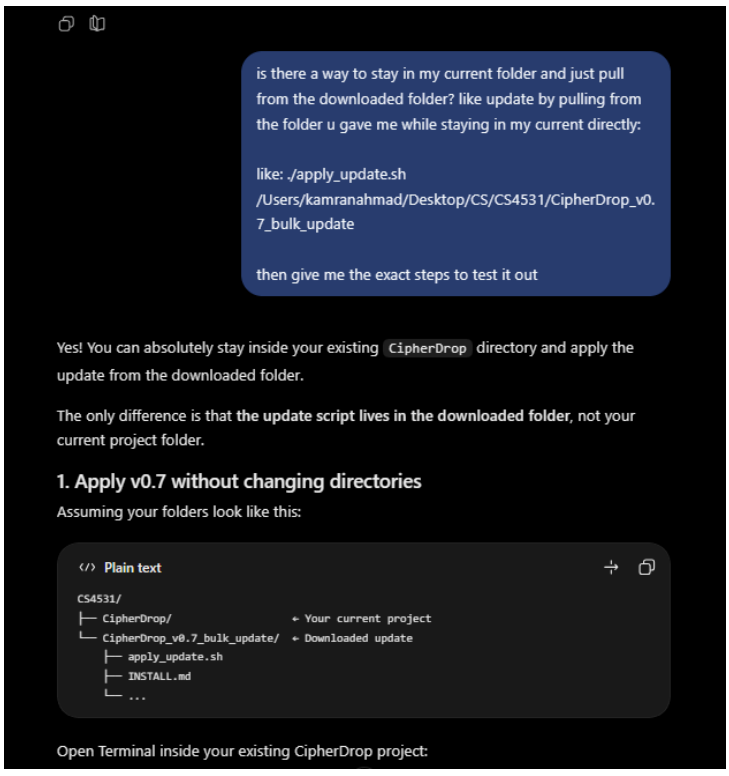

We did not use much AI specifically for password management and the storage of that within databases along with hashes, in the first place its widely considered an issue to do so and anthropic itself has made a terminal version that can be used just for that reason to ensure that hashing and encryption algorithms are kept private and secure.

We also specifically used AI for the purpose of generating test cases, we created 12 of these test cases which would go through several different parts of the application and ensure that they generated the correct output for each input. We made test cases to ensure the security sessions, audit chain, download limits, and audit chain verifications were successful along with a couple of other things. We had also used chatGPT to fix a lot of merge conflicts and git errors that occurred, mainly due to different branches pushing to the wrong areas or pulling when another person had pushed their own code prior to that. On a side note we also used ChatGPT for the generation of random testnames and testpasswords, these would be used so you could log in to that specific level of authorization in order to test something. For example there would be a simple prompt that would ask what's an easy testname we could use to log in to our admin account that's memorable and it would give us something like that, all testnames are to be deleted when the project is finished naturally since they appear on the main screen for easy testing.

All in all AI was pretty useful for many things. Specifically, locating buggy code, frontend, test cases, and formatting along with teaching anything we didn't know. However, we did have some trouble with debugging that buggy code, backend code generation, and frontend issues with styling. These things however could be corrected with human input so overall I would say that while difficult to completely maintain, AI was helpful for this project.

```

For the **Transcripts** section, paste your actual AI interactions. You cannot generate fake transcripts — they must be real conversations from your project.

```

Today 11:06 AM

test 0.5 works
test 0.6 works, i can see the activity in the activity tab, but when i click verify chain in the security tab, it just shows verified 12 events thats it
test 0.7 works too
next steps now? or do we push to github first to get another commit and then do the next few features?

Yes! Let's push v0.7 to GitHub first, then immediately move on to the next batch of features. 🚀

You've successfully tested all three major systems:

Version	Feature	Status
v0.5	Security Sessions	✅ Working
v0.6	Activity Timeline	✅ Working
v0.6	Audit Chain Verification	✅ Working
v0.7	Encrypted Secure Links	✅ Working
v0.7	Download Limits & Revocation	✅ Working

About "Verified 12 Events"

That's exactly what we want!

When CipherDrop displays:

Verified — 12 Events

It means the verifier checked 12 audit recor nd found no integrity violations.
